BRAINTEASER!

I'm driving out to a resort, which is pretty far away. Luckily, the first three quarters of the distance is all highway driving, but I have to drive the rest on slower local roads. I drive at 60 mph on the highway, but only 20 mph on local roads. What's my average speed for this trip?

ANSWER:

You might think you can just take a weighted average of the two speeds, and conclude the answer is just $\frac{3}{4} \times 60 + \frac{1}{4} \times 20 = 50$ mph, but that's not correct! This is because average speed is calculated by averaging speed over time, not over distance.

Solution:

Let x be the total distance to the resort. The time you spend on the highway is $\frac{\frac{3}{4}x}{60} = \frac{x}{80}$ hours, and the time you spend on the local roads is $\frac{\frac{1}{4}x}{20} = \frac{x}{80}$ hours. Then your average speed is $\frac{x}{\frac{x}{80} + \frac{x}{80}} = 40$ mph.

KEY DEFINITIONS

Call Option

- An agreement that gives the buyer the right, but not the obligation, to buy an underlying asset at a specified price within a specific time period

Put Option

- An agreement that gives the buyer the right, but not the obligation, to sell an underlying asset at a specified price within a specific time period

OTHER KEY TERMS TO KNOW

- S** - Price of Underlying Asset
- F** - Forward (Futures) Price of Underlying Asset
- K** - Strike (Exercise) Price
- t** - Time to Expiration
- r** - Rate of Interest
- σ** - Volatility
- C** - Call Price
- P** - Put Price
- q** - Dividend Yield

The forward (F) is more “important” than spot (S).
Why?

2 TYPES OF OPTIONS

American Options – buyer can exercise option early

European Options – buyer cannot exercise option early and has to wait until expiration

PAYOFF DIAGRAM FOR BUYING A CALL

PAYOFF DIAGRAM FOR BUYING A PUT

EARLY EXERCISE OF AMERICAN PUTS

American Options – buyer can exercise option early

Why would someone ever exercise their option early?

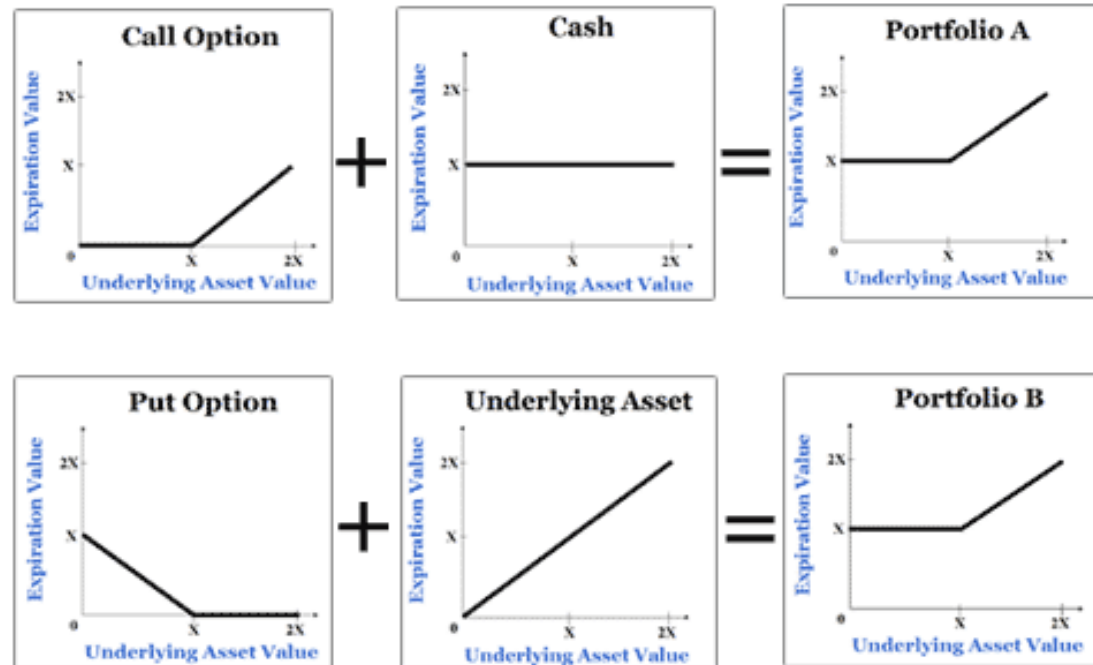

PUT-CALL PARITY

- Defines the relationship between the price of a European put and European call of the same class (same strike/underlying asset/expiration date)

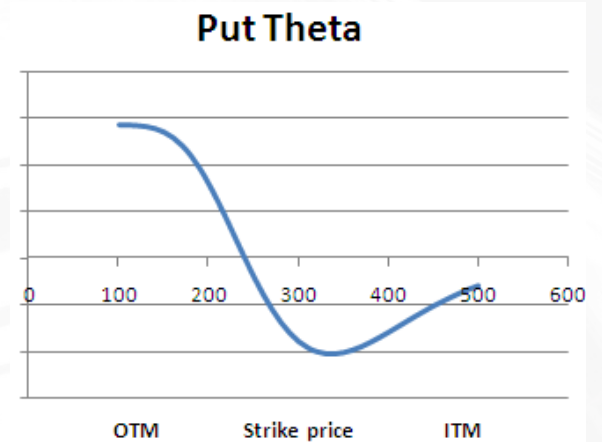

PUT-CALL PARITY

- $P + S = C + PV(K)$
- $C = P + S - PV(K)$

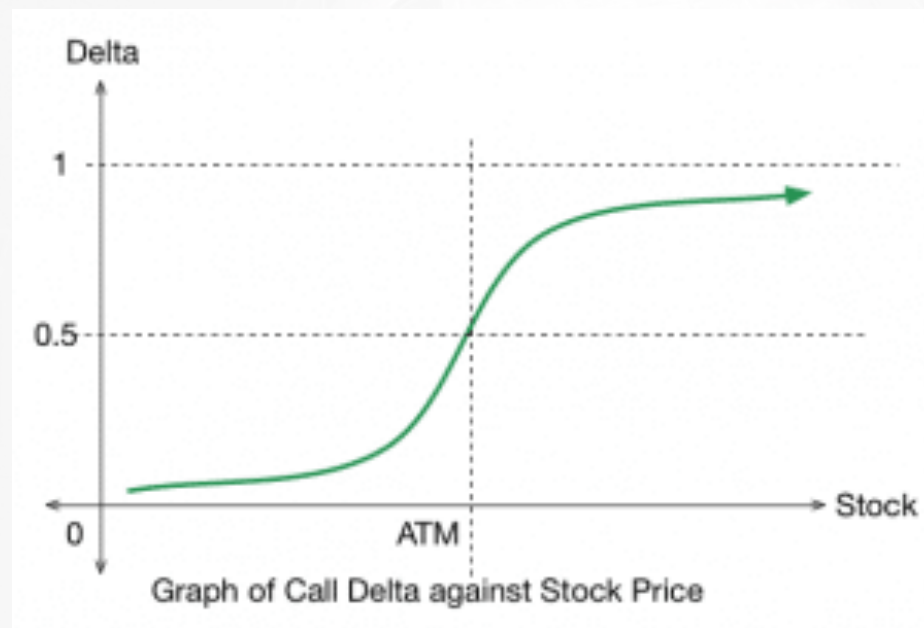

THETA

- Change in value of option as you move closer to expiry (time decay)

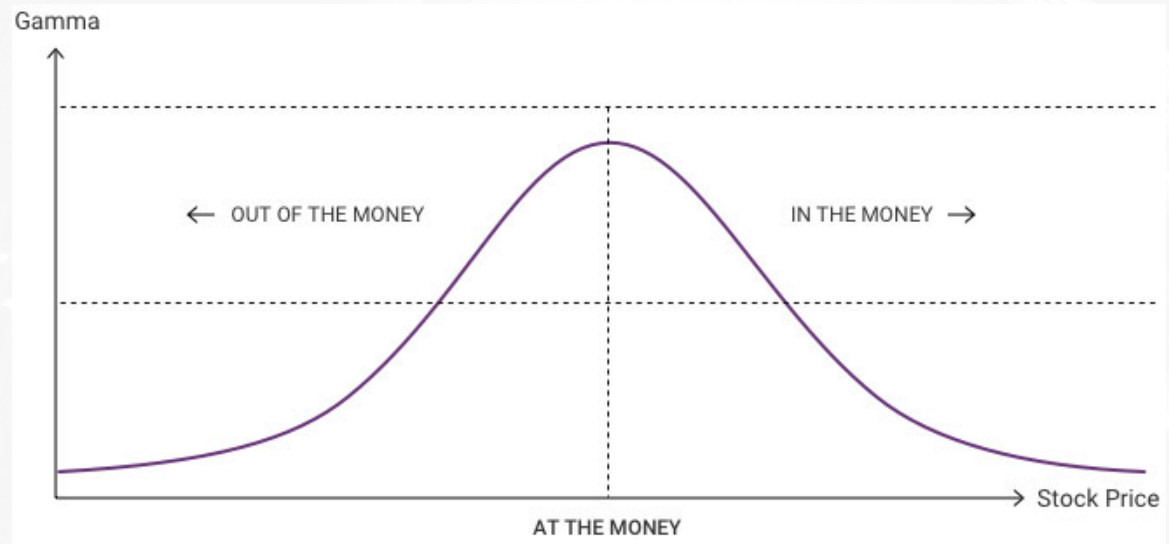

DELTA

- Change in price of option for every dollar movement in underlying

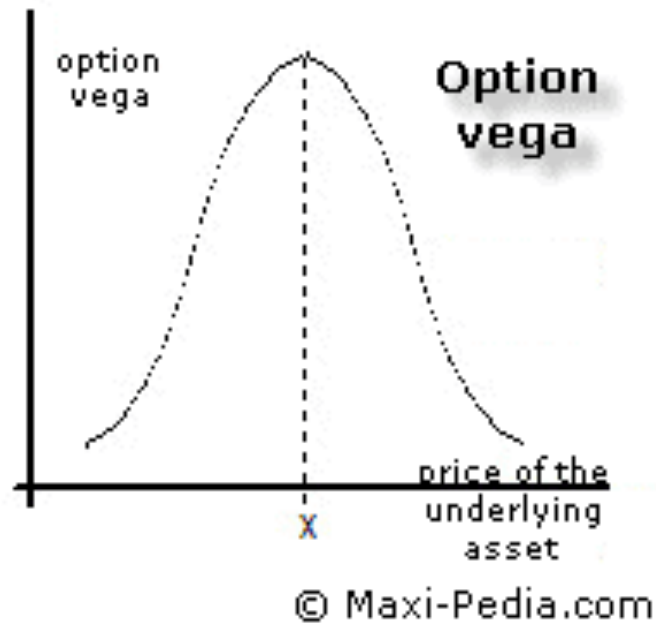

GAMMA

- Second derivative of delta – measures rate of change in delta

VEGA

- Price sensitivity to 1% change in volatility of underlying

RHO

- How sensitive options pricing is to interest rates

VOLATILITY SKEW

- Measures implied vol (demand) of options
- Skew: spot-vol relationship
- Smile: positive vol convexity
